A comparative environmental impact analysis of asphalt mixtures containing Crumb Rubber and Reclaimed Asphalt Pavement using Life Cycle Assessment

The research work presented in this paper aims at evaluating the potential environmental impacts of asphalt mixtures containing crumb rubber (CR) (vulcanized or devulcanized) and reclaimed asphalt pavement (RAP) assuming different degree of blending between aged and virgin binder by means of a life cycle assessment (LCA). The LCA allows comparing distinct alternatives according to their environmental performance across a set of impact categories. The results of the case study showed that when compared with a traditional asphalt mixture, the CR modified (CRM) mixtures caused higher impacts due to the treatment of the rubber as well as the higher amount of bitumen employed in the mixture. In turn, for mixtures containing RAP the analysis revealed an improvement of all the environmental indicators considered. Moreover, the potential environmental benefits of all impact categories were found to increase linearly when the degree of blending between the aged and virgin bitumen increases.

Keywords: Life cycle assessment; crumb rubber; devulcanization; RAP; base course; road sustainable materials.

1. Introduction

Reclaimed Asphalt Pavement (RAP) and End-of-Life tires (EOLTs) are among the most popular recycling materials to be used in road construction and maintenance (Silva *et al.* 2012, Bressi *et al.* 2016). The massive use of these materials that have the potential to replace non-renewable resources, is very attractive because it may lead to the reduction of a set of environmental burdens, such as the greenhouse gas (GHGs) emissions and energy consumption (Farina *et al.* 2017). EOLTs are among the largest and most problematic sources of waste due to the large volume produced and their durability (Lo Presti 2013). While these characteristics are negative if EOLTs are considered as waste material, the fact that crumb rubber modifiers (CRM) obtained from the processing of EOLTs are very resistant and durable make them an interesting material for use in other products, such as asphalt mixtures.

Rubber grains obtained from the treatment of crushing scrap tires in specialized plants can be incorporated into the preparation of asphalt mixtures by the so-called “wet” and “dry” production processes. The wet process describes the dissolution of the CR in the bitumen as a modifying agent. The dry process describes the replacement of a small portion of aggregates with the same fractions as those of the rubber grains (FHWA 1997).

The re-use and recycling of RAP in the construction and maintenance of infrastructure is a well-known practice that has been object of several research efforts towards maximizing the quantity of RAP employed in the production of new asphalt mixtures (Bressi *et al.* 2016). The use of RAP avoids the land use change, since the landscape is often ruined by disused quarries (Puppala *et al.* 2012). Moreover, the aged binder contained in RAP can act as the virgin binder (VB), which allows reducing the addition of new binder. In this context, the quantification of the Degree Of binder Activation (DoA) defined as the amount of RAP binder that can be considered “active” in the new formulation of asphalt mixtures incorporating RAP, has raised the interest of the scientific community (Shirodkar *et al.* 2011, Castorena *et al.* 2016, Cavalli *et al.* 2016) because the increase of the aged binder mobilized in a new mixture can be seen as a potential way to reduce the consumption of non-renewable resources such as the bitumen.

1.1. Vulcanized and devulcanized rubber for asphalt mixtures

To produce tires, the rubber undergoes a vulcanization process by using sulfur, peroxides and other substances intended to prevent the tires from cracking and to improve their properties (Rafique 2012). Vulcanization therefore is a process where chemical bonds are created between sulfur and the carbon molecules of rubber. Devulcanization refers to the process in which the crosslink bonds in the vulcanized rubber are selectively broken, cleaving the sulfur-sulfur or carbon-sulfur bonds and shortening the molecular chains (Rader *et al.*

1
2
3 1995). Indeed, the three-dimensional network structure restrains the rubber from melting
4
5 (Fukumori and Matsushita 2003, Mangili *et al.* 2015). Therefore, the reclamation of scrap
6
7 tires is mainly related to shredding and devulcanization of CR (Rafique 2012). When rubber
8
9 is intended for use as element in wet or dry process for asphalt mixture, the use of reclaimed
10
11 rubber, i.e. devulcanized rubber that has regained its viscosity as well as the characteristics of
12
13 the original compound (ChemRisk(LLC) 2009), is preferable. In this case, a more
14
15 homogeneous blend with the binder may be obtained because the rubber acts mainly as a
16
17 flexible filler (Giavarini 1994, Gawel *et al.* 2006) that can be stored at high temperatures for
18
19 longer periods without having problems related to its sedimentation (Morrison *et al.* 1995).
20
21
22
23
24

25 The devulcanization process encompasses several steps. They can be summarized as
26
27 follows: (i) shredding the tires to small particles of rubber; (ii) fibers and steel removal
28
29 through the use of suitable separators, and; (iii) further grinding of the rubber to a finer size
30
31 and then mixture with different reclaiming agents (Rajan *et al.* 2006). The most studied
32
33 devulcanization strategies involve mechanical, chemical, physical, biological, microwave and
34
35 ultrasonic processes (Adhikari *et al.* 2000, Rafique 2012, Isayev 2013, Mangili *et al.* 2015).
36
37
38
39

40 Shredding is the first stage of the entire process of rubber reclamation and it pulverizes
41
42 the scrap tires into a fine powder from 10 to 30 mesh (Li *et al.* 2014). Specifically, ambient
43
44 grinding is a multi-step technology where tire chips are crushed in mills at ambient
45
46 temperature (Shu and Huang 2014). The chips are fed into a granulator that breaks them into
47
48 small pieces. Afterwards, the remaining steel is removed magnetically, while for the fiber a
49
50 combination of shaking screens and wind sifters are used. Other important shredding
51
52 processes for producing CR are the cryogenic and water jet processes (CalRecovery 2004).
53
54
55
56

57 After shredding, the rubber could be used either directly in a vulcanized state, or it can
58
59 undergo the devulcanization process. It should be noted that the size of the rubber particles is
60

1
2
3 responsible for the effectiveness of the devulcanization processes. Certain process requires
4 fine particles, other can tolerate coarser rubber particles (CalRecovery 2004).
5
6
7

8 9 **1.2. RUMAC technology**

10
11 When CR is used as a portion of aggregates in hot mixture asphalt (HMA), the
12 resultant product is sometimes referred to as rubber-modified asphalt concrete (RUMAC).
13
14 This type of mixture usually contains a rubber percentage that varies from 1 to 3 percent by
15 weight of the total aggregate in the mixture and a target air voids content that varies from 2 to
16 4 percent (FHWA 1997). In the 1980's the mixture design and the technology were refined,
17 given origin to the production of an asphalt mixture commercially called PlusRide (Kandhal
18 and Hanson 1993).
19

21
22
23
24
25
26
27

28 The long-term performance of CRM using dry process need to be further studied (Cao
29 2007), because of the higher uncertainties characterizing the performance of dry process
30 compared to the wet process (Santagata et al. 2016). Indeed, the use of CR for dry process
31 contributes to create a complex scenario regarding the performance of the mixture because
32 there are many variables affecting the results that could yield to an inconsistent performance
33 record, with non-negligible problems related to homogeneity and compaction (Santagata et al.
34 2016, Bressi et al. 2018a). Nevertheless, controlling bitumen–CR interactions and other
35 fabrication parameters in dry mixtures it is possible to obtain beneficial effects (Khalid HA
36 and Artamendi I., 2002). Moreover, undoubtedly the dry process, using rubber particles much
37 coarser than wet process, facilitates the industrial production. The amount of rubber can be
38 significantly higher (the dry process can use from 2 to 4 times as much as the wet process),
39 increasing the rate of the recycling material and the incorporation in the mixture is easier (in
40 the dry process there is no need of special equipment, while in the wet process special mixing
41 chambers, reaction and blending tanks, and oversized pumps are required) (Roberts *et al.*
42
43

1
2
3 1989). Referring to low noise pavements, according to some Authors, when using the dry
4 process in experimental sections, the noise absorption can be significant and higher if
5 compared to the wet process (Paje *et al.* 2010, Losa *et al.* 2012); it seems this effect is
6 amplified by the devulcanization treatment (Zhang *et al.* 2013). The improvement of the
7 acoustic absorption is attributed to the improved chain flexibility of the molecules after the
8 devulcanization treatment (Liang 2013).

12
13
14
15

16
17
18 Several studies exist in the literature that compare the performance and the durability
19 of CRM materials. However, only a few of them have analyzed the potential environmental
20 benefits derived from the use of these recycled materials (vulcanized or devulcanized rubber)
21 for road pavement construction.
22
23
24
25

26
27
28 For these reasons, in this paper different combinations of percentage of rubber and
29 rubber treatments used in the dry process RUMAC technology for asphalt mixtures are
30 compared in order to evaluate the potential reduction of the environmental burdens arising
31 from the use of these material and technologies in the production of asphalt mixtures.

37

38 39 **1.3. Degree of activated aged binder in RAP mixtures**

40 Combining RAP with virgin materials introduces some unique challenges, as the RAP
41 materials contain aged bitumen that often is considered as inactive ("black rock"). However,
42 experience shows that "black rock" is not a priori inactive. The other scenario normally
43 considered is the "full blending". "Full blending" assumes that 100% of the RAP binder is
44 reactivated, binding and covering aggregates in the new mix, whereas "black rock" considers
45 that 0% of the binder will be active and the RAP behaves as a rock. In between these two
46 extremes, more reasonably it is considered that the aged binder contained in RAP does not act
47 in a new mixture just like a "black rock", and also not 100% reactivated at high temperatures.
48
49
50
51
52
53
54
55
56
57
58
59
60 A more reasonable assumption is that the DoA is located between these two points.

1
2
3 Quantifying the level of DoA in RAP mixtures is important for mix design purposes
4
5 because allows reducing the amount of VB employed in the mixture (Coffey *et al.* 2013) and
6
7 would bring higher level of reliability in the overall process of design, production and
8
9 compaction of asphalt mixtures containing high quantity of RAP.
10
11

12
13 Despite the research efforts dedicated to investigate the behavior of aged binder in
14
15 recycled asphalt mixtures, there are not common and standardized procedure for determining
16
17 the DoA (Lo Presti *et al.* under review) and the majority of the studies of the environmental
18
19 benefits related to the use of RAP assumes full blending between aged and VB (Ventura *et al.*
20
21 2008, Giani *et al.* 2015).
22
23
24

25
26 The fact that a common and standardized procedure is not clearly defined leads to high
27
28 level of uncertainties associated with the quantification of the DoA, which among other
29
30 factors, also depends on the characteristics of the RAP and VB.
31
32

33
34 Therefore, in the framework of this paper several DoAs in an asphalt mixture
35
36 containing 40% of RAP were considered to analyze the environmental benefits derived from
37
38 the reactivation of the aged binder and the reduction of the use of VB.
39
40

41
42 As suggested by the traditional approach recommended by many authors for mixtures
43
44 containing more than 25% of RAP (Kandhal and Foo 1997, McDaniel and Anderson 2001,
45
46 Zhou *et al.* 2011), blending charts should be used for selecting the type and content of the VB
47
48 or Recycling Agents (RA). Soleymani *et al.* (1999) and Shen *et al.* (2007) recommended the
49
50 use of softer binders in mixtures with 30–40% of RAP, while rejuvenators should be used in
51
52 mixtures with higher percentages of RAP. Therefore, in the study presented in this paper the
53
54 rejuvenators were not considered, given that the RAP content of the mixtures studied was
55
56 within the range of 40%.
57
58
59
60

1
2
3 Furthermore, controlling the mixture gradation with fractionation of RAP, asphalt
4 mixture interaction and compatibility between RAP and virgin materials is important in
5 producing consistent performing mixtures maximizing their durability (Colbert and You
6 2012).
7

12

13 **2. Objectives and Methodology**

14
15 A life cycle approach is crucial to identify and quantify the potential environmental
16 benefits derived from the use of alternative materials in asphalt mixtures.
17
18

19
20 This need can be fulfilled with the support of the life cycle assessment (LCA)
21 methodology, which is a data-driven, systematic methodology, that has proven to be effective
22 in estimating the potential environmental burdens caused by a product, process, or service
23 throughout its life cycle (Matthews *et al.* 2015). Among other capabilities, LCA does not only
24 assesses the potential environmental impacts of the outputs released to the environment
25 because of the energy and material consumed, but also identifies opportunities for
26 environmental improvements.
27
28
29
30
31
32
33
34
35

36 The LCA study is performed taking into account as much as possible and suitable the
37 ISO 14040 and ISO 14044 series (ISO 14040, ISO 14044), the Federal Highway
38 Administration's (FHWA's) Pavement LCA Framework (Harvey *et al.*, 2016) and the ILCD
39 Handbook (European Commission - Joint Research Centre - Institute for Environment and
40 Sustainability 2010).
41
42
43
44
45
46
47

48 The next sections thoroughly report the LCA study performed in the research work.
49
50
51

52 **2.1. Goal and scope definition**

53 **2.1.1. Intended applications**

54
55 This study aims to perform a comparative LCA of traditional Italian asphalt mixtures
56 and certain innovative mixtures containing different percentages of recycled materials (i.e.,
57
58
59
60

1
2
3 RAP and CR), employed in the base course of flexible road pavements. Specifically, the CR
4
5 obtained from processing EOLTs (ambient grinding and devulcanization process) and the
6
7 RAP coming from the demolition of old road pavements considering different DoA were
8
9 considered. The results are compared with those associated with the use of traditional
10
11 mixtures and are intended to provide insights on the extent to which recycling based materials
12
13 with similar features to those considered in this case study and employed in analogous
14
15 situations, are efficient in contributing to greening the road pavement sector.
16
17

18 19 2.1.2. *Reasons for carrying out the LCA study and target audience*

20
21 The main reason underlying to the performance of this study has to do with the fact it
22
23 is believed to provide valuable information to be incorporated at the early stages in the design
24
25 of new or in the maintenance of existing pavement structures. The findings of this study are
26
27 intended to be used by engineering experts and practitioners for evaluating the advantages and
28
29 disadvantages associated with the use of emerging and commonly called sustainable strategies
30
31 and practices for road pavement construction, maintenance and rehabilitation (M&R). Indeed,
32
33 this study quantifies the potential benefits resulting from the consideration of different DoAs,
34
35 by developing different equations that show the evolution of the reduction of the scores of
36
37 each impact category indicator when different DoAs are assumed. Furthermore, the concerned
38
39 audience is provided with the results of a comparative and seldom performed LCA study
40
41 between the use of vulcanized and devulcanized rubber in the road pavement construction.
42
43
44
45

46
47 The system includes, within its boundaries, all the activities required to construct the
48
49 asphalt base course layer. Specifically, the following phases are accounted for: (i) resources
50
51 extraction and composite materials production; (ii) movement involved in hauling the
52
53 materials between facilities and work site; and (iii) construction equipment operation during
54
55 the construction of the base course layer.
56
57

58 2.1.3. *Function, functional unit and reference flows*

1
2
3 *Function:* The different asphalt mixtures are made of different materials and compared
4
5 considering their main function when used in a structural layer of a road pavement structure.
6
7 Their aim is to distribute loads to the layers beneath, thereby contributing to ensure safe,
8
9 comfortable, economical, and durable driving conditions over a given project analysis period
10
11 (PAP).
12
13

14 *Functional unit:* All the asphalt mixtures are compared on the basis for the following
15
16 functional unit: Help to enable a given volume of traffic to drive with safe, comfortable,
17
18 economical, and durable conditions in a 1 km-length principal Italian rural roadway, located
19
20 in Empoli (Tuscany), with 2 carriageways and 4 lanes and a base course layer which is 10 cm-
21
22 tick and 15 m-wide. The thickness is equal for all the alternatives since it is assumed that all
23
24 the solutions have the same durability. The rationale behind this assumption is presented later
25
26 in this paper with more detail.
27
28
29

30 *Reference flows:* Considering that all the alternative asphalt mixtures are assumed to
31
32 have the same durability, The quantity of asphalt mixtures corresponding to a unitary
33
34 application of such mixtures in the base course with the dimensions described above is
35
36 considered as the reference flow.
37
38
39

40 In total, eleven types of asphalt mixtures intended to be applied in base course are
41
42 considered in the case study: the traditional mixture, complying with the Italian standards, and
43
44 ten alternative mixtures with recycled materials, i.e., different quantities of CR and RAP.
45
46

47 To understand the potential environmental advantages and disadvantages related to the
48
49 use of asphalt mixtures with recycled materials, different percentages of RAP and CR are
50
51 considered and compared with the reference scenario corresponding to the production and
52
53 placement of a classical asphalt mixture named “Base” with 4.5% of bitumen by weight of
54
55 mixture. The mixtures considered have the features described below (the percentages are
56
57 given by weight of mixture):
58
59
60

- 1
2
3 • DRY1.5D - Rubberized asphalt mixture (RUMAC dry process) containing 1.5% of
4 devulcanized CR and 5.5% of bitumen;
5
6
- 7
8 • DRY2.0D - Rubberized asphalt mixture (RUMAC dry process) containing 2.0% of
9 devulcanized CR and 6.0% of bitumen;
10
11
- 12 • DRY1.5V - Rubberized asphalt mixture (RUMAC dry process) containing 1.5% of
13 vulcanized CR and 5.5% of bitumen;
14
15
- 16 • DRY2.0V - Rubberized asphalt mixture (RUMAC dry process) containing 2.0% of
17 vulcanized CR and 6.0% of bitumen;
18
19
- 20 • RAP40BR - asphalt mixture with 40% of RAP in partial substitution of virgin
21 aggregates. This scenario considers that the bitumen trapped in RAP behaves as black
22 rock (Shirodkar *et al.* 2011), and then it is not active in the new asphalt mixture.
23
24 Therefore, the percentage of the VB to be added to the mixture cannot be reduced and
25 was kept equal to 4.5%;
26
27
- 28 • RAP40DOA20, RAP40DOA50, RAP40DOA70, RAP40DOA80 - asphalt mixtures
29 with 40% of RAP in partial substitution of virgin aggregates. This scenario considers
30 that the bitumen trapped in RAP partially blends (DoA equal to 20, 50, 70 and 80%)
31 with the VB.
32
33
- 34 • RAP40FB - asphalt mixture with 40% of RAP in partial substitution of virgin
35 aggregates. This scenario considers 100% of aged bitumen trapped in the RAP being
36 reactivated. The full blending between the RAP and VB allows reducing the portion of
37 VB. The RAP binder content is 5.3%. Therefore, it is necessary to add 2.4% of VB in
38 order to have a final content of 4.5% of total bitumen by weight of the mixture.
39
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54

55 The bitumen selected for the RUMAC dry process mixture is similar to the one used
56 for the traditional asphalt (FHWA 1997). The size of rubber grains ranges from 4.75 mm to
57 0.075 mm. The target air voids content of the asphalt mixture was defined to be equal to 3%.
58
59
60

1
2
3 The compositions of DRY1.5D, DRY1.5V, DRY2.0D and DRY2.0V mixtures were obtained
4 from the mix design performed in previous studies in which were shown that higher amounts
5 of rubber can inhibit a satisfactory compaction in the laboratory of dense graded asphalt
6 mixtures due to the elastic behavior of the rubber (Bressi *et al.* 2018a). Due to this reason,
7 higher percentages of rubber were not considered. Moreover, rubber absorbs the oil fraction
8 of bitumen in the so-called maturation process (Dong *et al.* 2012); this causes the swelling of
9 the CR particles and leads to the need of adding higher quantity of VB. Indeed, when the
10 rubber is added to the asphalt mixture by means of the dry process, the grains of rubber swell
11 up because they absorb part of the volatile parts of bitumen (paraffin and maltenes). This
12 process of maturation, called “maceration”, originates a stiffer bitumen (Dong *et al.* 2012),
13 therefore increasing the quantity of bitumen necessary to achieve the optimal mix design of
14 the CR mixtures. Tables 1-2 summarize the composition of each asphalt mixture used as
15 alternative to the traditional asphalt mixture.

38 *2.1.4. LCI modelling framework*

39
40
41
42 Given that the eventual use of the new asphalt mixtures is not expected to have large
43 structural changes in the market, the decision context falls into the situation A in the ILCD
44 Guideline (European Commission - Joint Research Centre - Institute for Environment and
45 Sustainability 2010), i.e. is micro-level, product or process-related decision support studies.
46 As such, the attributional approach was chosen as the life cycle inventory (LCI) modelling
47 framework. The attributional approach depicts the actual or forecasted specific or average
48 supply-chain. Also, it assumes that the decisions made within the system that produces and
49 uses the asphalt mixtures do not influence the “outside world” (Hertwich 2014).
50

2.1.5. System boundaries

The system boundaries tailored for the specific application considered in this research work took into account the existing literature on the durability and performance of asphalt mixtures containing CR (dry process) and/or RAP. In this context, according to several studies (McDaniel *et al.* 2000, Cao 2007, Farina *et al.* 2017), the performance of mixtures containing dry CR and RAP can be considered to be similar to that of traditional mixtures if they are properly designed to avoid non negligible problems related to homogeneity and compaction of the mixture (Santagata *et al.* 2016). A few others studies, instead, report higher performance (Airey *et al.* 2003, Huang *et al.* 2004, Hernandez-Olivares *et al.* 2009). In the particular case of the devulcanization process, it emerges that at low temperatures the asphalt mixtures containing devulcanized rubber perform better than traditional ones. Nevertheless, at high temperatures, the devulcanized rubber provides only a modest improvement, because the elastic properties of the rubber are damaged due to the devulcanization/depolymerization effect (Han *et al.* 2016). It should be also considered that a small amount of residual solvent used during the devulcanization process can have a significant effect on the binder properties at high and low temperatures (Morrison *et al.* 1995). Despite the potential benefits in terms of asphalt performance, derived from the use of devulcanized rubber at low temperature (Morrison *et al.* 1995), additional research is currently needed to improve the technology and the incorporation of the rubber into the asphalt mixture to ensure higher durability of the final product. These materials, in particular the RUMAC technology analysed in this paper, have also been tested several times in test sections showing contradictory results. For instance, the California Department of Transportation (CalTrans) has constructed four projects using the PlusRide dry process technology and the results showed that two of the four dry process projects improved the performance of traditional dense-graded asphalt, while a third project has performed comparably and the last one showed worse results (Kirk 1991). Moreover, the

1
2
3 two dry process sections constructed by the Minnesota Department of Transportation
4 (MNDOT) have not shown higher performance compared to traditional asphalt (Turgeon
5 1989). The Washington State DOT (Estakhri *et al.* 1992) concluded that the RUMAC dry
6 process did not provide improved performance compared to conventional asphalt. Therefore,
7 a conservative approach assuming the same durability for all the solutions was considered.
8 That means that the maintenance, dismantling and disposal phases are scheduled at the same
9 time for all the solutions and then were excluded from the system boundaries. Indeed, a
10 cradle-to-gate model is appropriate when the materials do not differ in durability, i.e. they
11 have same construction, transport implications, maintenance and EOL management
12 (European Commission - Joint Research Centre - Institute for Environment and Sustainability
13 2010). Due to these facts, these phases were excluded from the compared systems. This
14 approach has also been adopted in recent studies comparing the use of materials with RAP in
15 infrastructures, when the durability was similar (Porot *et al.* 2016). Indeed, the use of RAP
16 percentages below 30–40% do not require usually specific technologies, such as separate
17 parallel drum or the use of additives to overcome technical issues. These percentages allow
18 for achieving the same durability of traditional mixtures without the employment of particular
19 technologies. Therefore, a cradle-to-gate approach could be considered (Porot *et al.* 2016).
20 This approach was also preferable in this case study because it allows a better isolation and
21 identification of the potential environmental benefits derived from the different DoA
22 scenarios.

23
24 Notwithstanding the considerations presented previously, the modelling approach
25 considered in this case study went beyond the cradle-to-gate, in the sense that the construction
26 and transportation of materials phases were also considered. An elaborated description of the
27 phases considered in this case study is provided next.

1
2
3 The resources extraction consists of the acquisition and processing of raw materials,
4 such as the bitumen production at refinery; extraction, crushing and sieving of aggregates;
5
6
7 acquisition of CR generated as a by-product of the scrap tires, ambient grinding,
8
9
10 devulcanization and RAP processing.
11
12

13 The composite materials production phase consists of the production of the asphalt
14 mixtures. It takes place in a batch-type hot mix production plant where the bitumen is heated
15 and pumped. Virgin aggregates are washed, dried, heated and then added to the mixture. The
16
17
18 CR is added at room temperature while RAP is heated at lower temperatures compared to the
19
20
21 virgin aggregates. Indeed, it is important to heat the RAP as little as possible, as the heating
22
23
24 process further ages the already aged binder (Cavalli et al., 2016). Next, once arrived at the
25
26
27 construction site, the asphalt mixtures are laid down with specific construction equipment and
28
29
30 machinery, such as standard pavers and rollers.
31
32

33 Finally, the transportation of materials phase refers to the hauling movements of
34
35
36 materials, to and from the construction site and between intermediate facilities.
37
38

39 2.1.6. Basis for impact assessment

40 The life cycle impact assessment (LCIA) stage of the standardized LCA methodology
41
42
43 comprises several steps, namely, classification, characterization, normalization, group and
44
45
46 weighting (ISO, 2006). Among these steps, classification and characterization were
47
48
49 undertaken in this study.

50 The characterization modelling to quantify the potential life cycle impacts was
51
52
53 performed by applying the impact assessment method ReCiPe according to the hierarchist
54
55
56 perspective (Goedkoop *et al.* 2013). Each perspective defined in the ReCiPe method (i.e.,
57
58
59 individualist, hierarchist and egalitarian) represents a hypothetical practitioner or decision
60
61
62 maker that has differences in moral beliefs, concerns and/or interests. This corresponds to a

1
2
3 specific set of preferences and contextual values that explains one's view on society and
4 nature (Hofstetter, 1998). The hierarchist perspective is based on the most common policy
5 principles with regards to time-frame and other issues (Goedkoop et al. 2013). The impacts
6 were modelled at midpoint level, rather than at endpoint level, in order to keep the uncertainty
7 as low as possible. Indeed, each aggregation step contributes to further increase the
8 uncertainty in the results (Hauschild and Huijbregts, 2015)
9

10
11
12 The aggregation of the different impact categories with their relative weights and
13 damage pathways was left to engineering experts and practitioners to make more assertive
14 judgments based on their own beliefs. Moreover, no normalisation was performed, mainly
15 because the existing reference values are thought to be underestimated for the toxicity-related
16 impact categories due to the insufficient knowledge of total emissions of the thousands of
17 different chemicals with toxicity potentials in Europe, thereby resulting in overestimation of
18 normalised impact scores for the freshwater ecotoxicity and human toxicity impact categories
19 (Laurent *et al.* 2011).
20
21
22
23
24
25
26
27
28
29
30
31
32
33
34

35 Summarizing, the following impact categories were considered: climate change, fossil
36 depletion, freshwater ecotoxicity, freshwater eutrophication, human toxicity, marine
37 ecotoxicity, marine eutrophication, particulate matter formation, terrestrial acidification,
38 ozone depletion, terrestrial ecotoxicity and water depletion. The "land use" impact category
39 was not considered in this analysis due to its high uncertainty (Latunussa *et al.* 2016).
40
41
42
43
44
45
46

47 The systems were modelled in Gabi Professional Academy LCA software® (GaBi ts
48 Software 7.3.3). The impact scores were calculated using the original set of ReCiPe (version
49 1.05) characterization factors as implemented in GaBi.
50
51
52

53 **2.2. Life Cycle Inventory**

54 The life cycle inventory (LCI) phase consists of the primary and secondary data
55 collection and the modelling of the system.
56
57
58
59
60

2.2.1. *Data collection and system modelling per life cycle phase*

Primary data are specifically related to the processes for obtaining the product or service studied in the LCA. In turn, secondary data represent generic or average data for the product or service subjected to an analysis. The provenience of that data includes literature, research groups, national and international database and expert's opinion (European Commission - Joint Research Centre - Institute for Environment and Sustainability 2010). In the present research work both primary and secondary data were considered as detailed in the following sub-paragraphs. The data sources were selected in order to be as much time, geographical and technological representative as possible. That means that the most recent and truthful data representing Italian processes and conditions were used as inputs when modelling the processes covered by the sub-components integrating the system boundaries. The Ecopneus document (Ecopneus 2013) was used as main reference for conducting the LCI of asphalt mixtures containing alternative materials. Reference values for the productivity and working hours of the machinery (pavers and rollers) considered for the laying down and compaction operations of the base course layers were collected from literature (Autostrade per l'Italia 2011). For completing the data set and modelling the background system, the *Construction materials* (CM) database extension of the Gabi software was used.

2.2.2. *Materials Extraction and Composite Materials in Production Phase*

2.2.2.1. *Virgin aggregates and bitumen production sub-phase.*

The virgin aggregates required for the base course layer were modelled as crushed gravel and the inventory data associated with their production were obtained from the CM database considering the percentage of the material passing at different sieves in a typical grading curve of base course. The dataset crushed rock 16-32 mm (40% of aggregates), crushed stone 2-15 mm (30% of aggregates) and crushed sand 0-2 mm (30% of aggregates) were selected. It

1
2
3 comprises all the flows of materials and energy associated with the extraction in the quarry,
4
5 the cleaning, the two stages of crushing and organization of the production. The finished
6
7 product is the crushed gravel (dried) at the factory gate. The CM database was also used as
8
9 the data source for modelling the bitumen production. In this case the dataset “Bitumen at
10
11 refinery; from crude oil; production mix, at refinery EU-27” was selected from the
12
13 *Professional database in Gabi software*. This dataset covers the entire supply chain of the
14
15 refinery products. That includes drilling, crude oil production and processing as well as the
16
17 transportation of crude oil via pipeline to the refinery. The production includes several
18
19 aspects, such as energy consumption, transport distances, crude oil processing technologies,
20
21 feedstock that are individually considered for each crude oil production country. The
22
23 inventory is mainly based on industry data and is completed, where necessary, by secondary
24
25 data.
26
27
28
29
30
31

32
33 **2.2.2.2. Crumb rubber production sub-phase.** A “cut-off” approach was adopted for
34
35 the evaluation of the burdens and benefits associated with the use of this recycled material.
36
37 According to this approach, only the impacts of the recycling process are attributed to the
38
39 second life cycle, while all the processes related to the production of the material before waste
40
41 are attributed to the first life cycle (Schrijvers *et al.* 2016). Therefore, only the burdens
42
43 directly associated with the product itself (crumb rubber) were accounted for. Two different
44
45 rubber treatments were considered: (i) the ambient grinding without chemical treatment of the
46
47 rubber, which produces vulcanized rubber, and; (ii) the devulcanization process, which
48
49 includes the rubber powder preparation (shredding and granulating), devulcanization (mainly
50
51 desulfurization) and refining of the rubber. All the stages of the rubber reclamation are
52
53 schematically represented in Figure 1.
54
55
56
57

58 **Figure 1**
59
60

1
2
3 Based on Figure 1, new processes related to the CR recycling, such as rubber
4 preparation (shredding and granulating), devulcanization and refining and collection in plastic
5 big bag, were created specifically for this analysis by collecting information from recent
6 studies conducted by Ecopneus (2013) and Li *et al.* (2014) and by using the *CM database*.
7
8
9
10
11
12

13 *Shredding and granulating.* The shredding and granulating is the first phase of the
14 rubber reclamation process, where the tires are crushed and broken into small pieces and the
15 remaining steel and fiber are removed magnetically. This process is performed with a
16 combination of shaking screens and wind sifters, without any chemical treatment of the
17 rubber.
18
19
20
21
22
23
24

25 In this phase the environmental impacts of the following processes were taken into
26 account: (i) transport of materials from the collection platform to the crushing plant; (ii)
27 crushing and separation of the fibers and metal from the rubber; and (iii) sieving of different
28 fractions.
29
30
31
32
33

34 For shredding and granulating phase it was necessary to build another sub-process:
35 *Steel blade* to crush the scrap tires conveyed in the batch through a conveyor belt for the
36 shredding and granulating.
37
38
39
40

41 For the steel blade production, the processes selected were as follows: (i) steel
42 production; (ii) hot rolling; and (iii) sheet rolling. The data set represents the steel production
43 based on the main production steps that take place within an integrated steel plant. The LCI of
44 the steel blade production process was collected from the recent study (Farina *et al.* 2017) and
45 it is represented by the processes “IT: electricity mix [supply mix]” (0.00103 MJ), “Steel,
46 converter, unalloyed, at plant”, “Sheet rolling, steel [processing]” present in CM database.
47
48
49
50
51
52
53
54
55 The input/output flows of materials and energy sources were calculated as the average value
56 of the data collected from the Italian crushing plants.
57
58
59
60

1
2
3 The CR production is a multi-output process. Indeed, from shredding and granulating
4 the scrap tires in specialized plants, three main elements can be obtained: (i) CR (that will be
5 used in the asphalt mixtures); (ii) scrap steel; and (iii) textile. Therefore, the allocation of all
6 the outputs was conducted according to the mass approach by using the following
7 percentages: 69% for the CR output; 20% for the scrap steel output; and 11% for the textile
8 output (Farina *et al.* 2017). Despite the high market value of steel, steel scrap was not
9 assumed to undergo recycling due to the high operational complexity of separating the scrap
10 steel from residual rubber. Table 3 summarizes the input and output flows of the CR
11 production process for producing 15 kg of rubber (1.5% of 1 ton of asphalt mixture).
12
13
14
15
16
17
18
19
20
21
22
23
24

25 **Table 3**

26
27 *Devulcanization and refining.* All the input and outputs of the devulcanization process
28 were collected from literature (Li *et al.* 2014). Specifically, plasticizers (pine tar and rosin)
29 were considered to be added to improve rubber plasticity after the shredding process. Pine tar
30 is a viscous and sticky liquid obtained from pine through destructive distillation. Rosin is
31 a solid resin obtained from the oil of pine trunk. The desulfurization tank is kept at a high
32 temperature (approximately 230°C) and under pressure (2.2 MPa). The waste gas discharged
33 in two different moments was treated. The first gas steam is discharged from desulfurization
34 tank, after it is cooled and decompressed. Finally, a gas absorber with sodium carbonate is
35 used to remove almost entirely the contaminants from the steam. The other one is discharged
36 from the heat conduction oil furnace and consists mainly of CO₂, NO_x and SO₂ (Li *et al.*
37 2014). A wet-flue gas desulfurization system, which rely on 96% efficiency in dust collection
38 and 75% desulfurization efficiency, was used. After the devulcanization process, the rubber is
39 reprocessed in the refining stage where non-methane volatile organic compounds (NMVOC)
40 are collected and absorbed with an efficiency of 80%. After that, they are released to the
41

3 atmosphere. Table 4 reports the input and output of the devulcanization and refining
4
5 processes.
6

7 8 **Table 4**

9
10
11 *Collection of rubber in plastic big bag.* The last step is represented by the collection of
12
13 rubber grains in plastic bag to be transported to the asphalt mix plant. It was assumed that the
14
15 plastic big-bag used for collecting the different fractions of rubber grains are composed of
16
17 90% of polypropylene and 10% of polyethylene. The process contains all the operations and
18
19 burdens for the transformation of raw plastic into the final product. The LCI data of the
20
21 plastic big bag production was collected from recent studies (Ruban 2012) and summarized in
22
23 Table 5.
24
25
26

27 28 **Table 5**

29
30
31 To collect 15 kg of rubber, i.e. final product to transport to the asphalt plant for
32
33 producing 1 ton of asphalt mixture (DRY1.5D and DRY1.5V), 0.028 kg of plastic big bag is
34
35 needed (Farina *et al.* 2017).
36
37
38

39
40 **2.2.2.3. RAP production sub-phase.** Also for the RAP production the “cut-off”
41
42 approach was adopted. In this case study, it was considered that once removed from road
43
44 pavement, the RAP is transported directly to the asphalt plant where it is stored in special
45
46 sites and subjected to screening and down-sizing operations. For the RAP handling, the
47
48 common production rates of the several machines were considered when determining the
49
50 energy requirements. The LCI data related to the production and distribution of those energy
51
52 resources was taken from the CM database. Moreover, the treatment of the RAP at the plant
53
54 requires a certain amount of energy for sieving and eventually crushing of the recycled
55
56
57
58
59
60

1
2
3 material. This amount of energy was considered to be equal to 0.0212 MJ per kg of RAP
4
5 (Zaumanis *et al.* 2012).
6
7
8

9 2.2.2.4. *Asphalt mixtures production sub-phase.* The asphalt mixture production
10 activities take a place in the hot mix production plant. The processes CR production,
11 aggregates production, RAP production and bitumen production already described were
12 created and fed into the process for the production of the asphalt mixtures. The electricity for
13 the production of 1 ton of any asphalt mixture was considered to be equal to 160 kWh
14 (Ecopneus 2013) based on the assumption that the mixing temperature is the same regardless
15 of the mixture being produced (Farina *et al.* 2017). In this case study the electricity was used
16 to power a discontinuous batch with a gas burner with a power of 580 kW.
17
18
19
20
21
22
23
24
25
26
27
28

29 2.2.3. *Construction Phase*

30
31 To build a layer of asphalt mixture in a road pavement it is necessary to lay down the
32 asphalt mixture with a paver and compact it in order to achieve the desired thickness of 10
33 cm. The fuel combustion-related emissions associated with the operation of each construction
34 equipment were determined by combining the LCI data corresponding to the process
35 “machine operation, diesel, ≥ 74.57 kW, high load factor” existing in the CM database with
36 an hourly productivity of 200 ton/h for the operations of the paver and 150 ton/h for the roller
37 involved in the pavement construction activities. By considering fuel consumption rates of 30
38 and 17 l/h (Autostrade per l’Italia 2011), respectively for a paver and a roller, the total fuel
39 consumption was calculated as 585 l/km (paver) and 332 l/km for the roller. The
40 consumptions were considered to be the same for all the alternatives proposed. Indeed,
41 regardless to the fact that recent studies (Bressi *et al.* 2018a) demonstrate the need of higher
42 compaction efforts of dry mixtures in the laboratory, there is no practical link between
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

laboratory increased compaction efforts and in-situ compaction in terms of the number of roller passages.

The airborne emissions caused by the lay down and compaction operations of asphalt layers increases with recycling rate. Therefore, the data coming from measurements performed by Jullien *et al.* (2006) was considered when modelling the construction process of the base course layer depending on whether or not the RAP is included in the mixture formulation.

2.2.4. *Transportation of Materials Phase*

Scrap tires, crushed gravel limestone, bitumen as well as plastic big bag, steel blade and subsequently CR must be transported between the production facilities, whereas the asphalt mixtures must be transported from the asphalt plant to the construction site. It was assumed that the materials are hauled from the quarry and plants by truck. Therefore, the environmental impacts resulting from the transportation of materials were due to the emissions released by the combustion process of the transportation vehicles. The process “GLO: Truck, Euro 3, 20 - 26t gross weight / 17.3 t payload capacity ts <u-so>” existing in the CM database was used to determine the environmental burdens associated with the transportation of materials hauled by heavy vehicles on the road.

The different processes adopted for the case study are outlined in Figure 2 for the rubberized mixtures and for the RAP mixtures. The transport distances between different sites are reported in Table 6.

Figure 2

Table 6

2.3. *Life Cycle Impact Assessment*

The characterized LCIA results are shown in Figure 3 and Figure 4. They highlight different aspects of the environmental performance associated with each alternative considered for the construction of the base course layer. In particular, Figure 3 displays the potential relative life cycle environmental impacts of the asphalt base course mixture containing vulcanized or devulcanized CR (i.e., DRY1.5V, DRY2.0V, DRY1.5D and DRY 2.0D) calculated in relation to those of the traditional asphalt mixture. The results are to be understood as follows: negative relative numbers mean that the alternative asphalt mixtures worsen the potential life cycle environmental impact results in relation to those associated with the traditional asphalt mixture while positive numbers represent an improvement of the environmental profile.

Figure 3

It can be observed that not only all the rubberized solutions lead to an increase of the scores of the whole impact categories set but also that the type of rubber treatment influences the environmental performance of the different solutions. Indeed, the devulcanization process leads to a significant increase of the environmental burdens compared to ambient grinding, especially in the case of the impact categories freshwater ecotoxicity, terrestrial ecotoxicity and water depletion. This can be confirmed in Figure 4 that displays the relative contributions of the several life cycle phases and sub-phases to the total impact category scores of the two types of rubberized asphalt.

Figure 4

As detailed in Figure 4, the asphalt mixtures production and base course layer construction phases are the main source of impacts for 7 out of 11 impact categories, followed by the bitumen production (4 out of 11 impact categories). In turn, the production of CR

1
2
3 (ambient grinding) is responsible by the lowest share of the impact scores. In the case of the
4 asphalt mixtures production and base course layer construction, their contribution can be as
5 high as 79.0% and 93.0% for the impact category particulate matter formation, respectively in
6 the solutions DRY2.0D and DRY2.0V, while the maximum contribution given by the
7 production of bitumen can amount to 69.3% and 73.2% for the impact category marine
8 ecotoxicity respectively in the solutions DRY2.0D and DRY2.0V. Regarding the production
9 of CR, its maximum contribution is observed for the impact category freshwater
10 eutrophication, being equal to 20.3% as the sum of rubber preparation, devulcanization and
11 refining for DRY2.0D and 3.0% for the ambient grinding for DRY2.0V in the case of
12 particulate matter formation. The devulcanization and refining have the highest environmental
13 burden in the rubber treatment because the desulfurization requires extensive heat from coal
14 combustion (Li *et al.* 2014). In the present case study, the highest impact category scores are
15 observed in the impact categories water depletion, freshwater eutrophication and climate
16 change. Therefore, to obtain a cleaner production, the focus must be placed on the flue gas
17 treatment in the devulcanization process. The results presented previously also confirm the
18 findings of other studies that reported the production of VB to be one of the most
19 environmental damaging and energy demanding processes in the road paving activity
20 (Santero *et al.* 2011, Santos *et al.* 2015, Farina *et al.* 2017, Bressi *et al.* 2018b).

51
52
53
54
55
56
57
58
59
60
Another important remark emerging from the results presented previously is that the use of rubberized asphalt mixtures can only be justified (from an environmental perspective) if the durability of the final product is higher. This is mainly due to the fact that the rubber grains are obtained from crushing scrap tires in specialized plants where they are also separated from steel fibers and textile. All these operations are extra compared to those required for producing conventional asphalt mixtures while the associated environmental burdens are not compensated by the amount of recycled material employed (only 1.5 or 2% of

1
2
3 CR). From the analysis of Figure 4 it emerges that when only ambient grinding is considered,
4
5 the CR production is not directly responsible of the higher impacts category scores of the
6
7 alternatives proposed. Instead, the higher quantity of bitumen required for the optimal mixture
8
9 design of the CR asphalt mixtures leads to considerable effects on the scores of all impact
10
11 categories, especially those related to the impact category ecotoxicity.
12
13
14

15
16 On the contrary, when the rubber is devulcanized, the desulfurization process requires
17
18 an extensive heat from coal combustion, and the emissions of the related flue gas contribute to
19
20 further increase of the environmental burdens.
21
22

23
24 Given that there is no clear evidence in the literature that the durability of the dry
25
26 mixtures is higher than that of traditional mixtures, it was assumed that the life cycle of the
27
28 layer constructed with the alternative mixtures is equal to that implemented with the
29
30 traditional solution. Therefore, the results in terms of durability of the layers and consequently
31
32 the life cycle environmental profile might have been different if the wet process had been
33
34 adopted to produce the alternative rubberized asphalt mixtures. In this case, the chemical
35
36 treatment of the rubber can improve the rheology of the binder thereby increasing the
37
38 performance of the overall mixture (Mangili *et al.* 2015).
39
40

43
44 Figure 5 shows the potential relative life cycle environmental impacts of the asphalt
45
46 mixtures containing RAP (RAP40BR and RAP40FB) in relation to those of the traditional
47
48 asphalt base course mixture. It can be observed that the solutions containing RAP reduce the
49
50 impact category scores compared to the reference solution in all the impact categories. In
51
52 particular, for the solution RAP40BR, which requires a lower quantity of virgin aggregates
53
54 and the same content of bitumen as that of the reference mixture, the impact categories marine
55
56 eutrophication (10.02%), freshwater eutrophication (6.59%), climate change (6.56%),
57
58 terrestrial ecotoxicity (6.41%) and particulate matter formation (6.22%) show the highest
59
60

benefits. It should be noted that when considering the full blending between the aged and VB and reducing the quantity of VB to be added to the RAP40FB mixture, the impact categories exhibiting the highest benefits are different: marine ecotoxicity (34.09%), fossil depletion (27.04%) human toxicity (26.83%), and freshwater ecotoxicity (24.07%). This means that the reduction by 40% of virgin aggregates has a greater effect on certain impact categories, while the bitumen reduction allows further reductions in all the impact categories, especially in the cases of the marine ecotoxicity, fossil depletion and human toxicity.

Figure 5

A more realistic assumption is made when the aged binder existing in RAP is considered to blend partially with the VB.

Figure 6 shows the potential life cycle impact category scores obtained when considering different DoA. From that figure it can be seen that as a consequence of the reduction in the use of VB, due to the increase in the DoA, the reduction of the potential life cycle impact scores derived from the incorporation of RAP in the production of asphalt mixtures are globally considerable for all the impact categories and follow a linear relationship. Table 7 displays all the numerical relationships derived from the potential life cycle impact category scores that relate the DoA of aged and VB with the potential relative benefit for each impact category.

Figure 6

Table 7

The table and figure introduced previously show that it is possible to define a ranking of improvement that depends on the VB to be added to the mixture. The ranking of the impact categories that have the highest benefits according to the equations derived from the analysis

1
2
3 are reported in Table 8 along with their specific range of improvement. The impact category
4 that benefits the most with the increase in the DoA is clearly the marine ecotoxicity, followed
5
6 that benefits the most with the increase in the DoA is clearly the marine ecotoxicity, followed
7
8 by fossil depletion and human toxicity. On the contrary, the impact categories ozone and
9
10 water depletion are found to be almost insensitive to changes in the DoA (improvements
11
12 inferior to 1%). Additionally, for DoA values approximately greater than 40% and lower than
13
14 10%, Figure 6 shows that the rankings of impact categories in terms of reductions in the
15
16 scores remained generally stable. This trend is different from that denoted for DoA values
17
18 ranging between approximately 10% and 40%, in which a change in the rankings is observed.
19
20
21

22 **Table 8**

23
24
25 Figure 7 shows the primary energy demand and climate change, expressed in terms of
26
27 CO₂-eq. emissions, derived from the production of asphalt mixtures containing recycled
28
29 materials in relation to those of the traditional asphalt base course mixture.
30

31 **Figure 7**

32
33
34 From Figure 7 it can be observed that the solutions containing RAP reduce the
35
36 primary energy demand and the CO₂-eq. emissions per ton of material in relation to those
37
38 associated with the reference solution. The energy required as well as the climate change
39
40 score decreases when the active aged binder increases, because there is a further reduction of
41
42 the VB needed to be added to the asphalt mixture. On the other side, as for all the other
43
44 environmental impact categories, the energy required for producing CRM mixtures increases,
45
46 especially if the rubber is treated with a devulcanization process before its use.
47
48
49
50

51 **3. Summary, conclusions and perspectives**

52
53
54 Currently, several research efforts are being undertaken to study the behavior of
55
56 innovative mixtures produced with a high content of recycled materials. Nevertheless, the
57
58 extent to which those mixtures are environmentally friendly remains to be assessed and
59
60

1
2
3 quantified. Therefore, this paper presents a comparative LCA of a traditional asphalt mixture
4 employed in the base course layer of a flexible road pavement and alternative asphalt
5 mixtures containing different percentages of recycled materials, namely RAP and CR.
6
7

8
9
10 The LCA is performed from the resource extraction and composite materials production to the
11 placement of the mixtures in the construction site, and including the movements of
12 transportation of materials. The results obtained show that:
13
14
15

- 16
17 • without an increase in the durability, the use of CR in asphalt mixtures leads to an
18 increase of the scores in all impact categories. For the CR mixtures, the amount of
19 bitumen increases as the amount of rubber in the mixture increases. That is due to the
20 fact that rubber absorbs the lighter parts of the bitumen in the so called process
21 “maceration”. The highest impact category scores are more pronounced in the case of
22 devulcanized rubber, because additional chemical treatments are required;
23
24
25
26
27
28
29
30
31
- 32 • due to the rubber elasticity, the rubberized asphalt usually recovers deformation after
33 the compaction phase. Therefore, by using a standard re-use of CR in asphalt
34 mixtures, the percentage of rubber in CR mixtures cannot be increased significantly.
35
36 As such, the small amount of CR used in this application does not justify all the
37 additional consumption of resources and emissions associated with its treatment;
38
39
40
41
42
- 43 • mixtures containing 40% of RAP reduce the scores of all the impact categories;
44
45
- 46 • further reductions of all the resources consumed and emissions released can be
47 achieved if the aged binder was fully reactivated and considered as VB, thereby
48 leading to a reduction of the amount of VB needed to be employed in a new mixture;
49
50
51
- 52 • the potential environmental benefits associated with all impact categories increase
53 linearly when the DoA between aged and VB increases. The impact categories that
54 showed the highest benefits when DoA increases are marine ecotoxicity, fossil
55 depletion and human toxicity;
56
57
58
59
60

- it is recommended the development and the use of additives able to reactivate the aged binder trapped in RAP, provided that the environmental impacts of their production, transportation and use do not offset the benefits obtained with the reduction of the use of VB.

To sum up, this study evaluated the environmental consequences of implementing innovative asphalt mixtures containing different percentages of recycled materials. The results show the negative effect deriving from the use of CR in the RUMAC technology. Nevertheless, certain potential benefits associated with the use of this technology were not considered, such as the reduction of noise and vibration. Therefore, the next steps of this research work will evaluate the sustainability of those materials by using a holistic and integrated approach that considers the three pillars of sustainability (environmental, social and economic).

Moreover, this research work opens the way to extend the study to other materials, such as, for instance, the assessment of the possible benefits derived from the use of rejuvenators (industrial or natural) when high RAP contents are used. The case study described and the results presented in this paper represents a first step in the study of the environmental performance of materials containing RAP. However, further studies are being performed to ascertain the effects of the rejuvenator on the total environmental impacts.

Finally, the availability of data to be used in the assessment of the environmental performance of these type of materials is still very limited. Therefore, further research efforts should be employed to produce a more complete and robust LCI that will certainly improve the overall quality of the LCA.

Table 1. Composition of the different asphalt mixtures containing CR used in the base course layer

Name of mixture	Description	Quantity of CR (kg per ton of mixture)	Quantity of bitumen (kg per ton of mixture)
Base	Traditional asphalt mixture (4.5% of bitumen)	0	45
DRY1.5D	Rubberized asphalt mixture (dry process) with devulcanized rubber (1.5% of rubber and 5.5% of bitumen)	15	55
DRY2.0D	Rubberized asphalt mixture (dry process) with devulcanized rubber (2.0% of rubber and 6.0% of bitumen)	20	60
DRY1.5V	Rubberized asphalt mixture (dry process) with vulcanized rubber (1.5% of rubber and 5.5% of bitumen)	15	55
DRY1.5V	Rubberized asphalt mixture (dry process) with vulcanized rubber (2.0% of rubber and 6.0% of bitumen)	20	60

Table 2. Composition of the different asphalt mixtures containing RAP with different simulations of degree of blending used in the base course layer

Name of mixture	Percentage of RAP (%)	Quantity of RAP (kg per ton of mixture)	Degree of blending (DOB) (%)	Activated old binder (%)	Percentage of virgin bitumen to add to the mixture (%)*	Quantity of bitumen to add to the mixture (kg per ton of mixture)	Quantity of virgin aggregates (kg per ton of mixture)
Base	0	0	0	-	4.5	45	555
RAP40BR	40	400	0	0	4.5	45	555
RAP40DOB20	40	400	20	0.4	4.1	41	559
RAP40DOB50	40	400	50	1.0	3.5	35	565
RAP40DOB70	40	400	70	1.5	3.0	30	570
RAP40DOB80	40	400	80	1.7	2.8	28	572
RAP40FB	40	400	100	2.1	2.4	24	576

*the total bitumen content active in the mixture is always 4.5%.

Table 3. Input and output flows associated with the CR production process

Input flow	Quantity	Unit
Diesel mix at refinery EU-28 ^a	0.038	Kg
IT: Electricity mix grid production ^b	20.7	MJ
Lubricating oil	0.001	Kg
Tap water, at user	3.3	Kg
Steel blade	0.004	Kg
Conveyor belt, at plant	9.5E-005	m
Scrap tires	21.8	Kg
Output flows	Quantity	Unit
CR (module created)	15	Kg
Recycled fibers	2.4	Kg
Steel scrap product	4.35	Kg

Notes: ^a This module includes the steam treatment and allows quantifying all the output of the diesel production; ^b It refers to the production and importation of energy in Italy, including all types of energy. It includes also losses, calculated as average values

Table 4. Input and output flows associated with the devulcanization and refining processes. The quantities refer to the treatment of 15 kg of rubber

Process	Input items	Quantity	Unit
Devulcanization	Coal tar [Organic intermediate products]	0.15	kg
	IT: electricity, high voltage, production IT, at grid [production mix]	68.2	MJ
	Purchased rubber powder [Plastic parts]	7.35	kg
	RER: rosin size, at plant [organics]	0.15	kg
	RER: tap water, at user	0.15	kg
	Rubber [Consumer waste]	7.35	kg
	Output items		
	Devulcanized rubber	15	kg
	Charcoal (loaded) [Hazardous waste for recovery]	0.675	kg
	Carbon dioxide [Inorganic emissions to air]	5.63	kg
Different pollutants [Other emissions to industrial soil]	0.0248	kg	
Nitrogen oxides [Inorganic emissions to fresh water]	0.0105	kg	
Sulphur dioxide [Inorganic emissions to air]	0.00675	kg	
Refining	Input items		
	Devulcanized rubber	15	kg
	IT: electricity, high voltage, production IT, at grid [production mix]	14.4	MJ
	Output items		
	Crumb recycled rubber	15	kg
NMVOC, non-methane volatile organic compounds, unspecified origin [ecoinvent long-term to air]	0.000555	kg	

Table 5. Inventory referring to the production of 1 kg of plastic big-bag

Input Item	Quantity	Unit
Diesel [Refinery products]	6,81E-05	kg
Polyethylene foam [Plastics]	1	kg
Polyethylene low density granulate (LDPE/PE-LD) [Plastics]	0,1	kg
Polypropylene granulate (PP) [Plastics]	0,9	kg
Emissions to air and water	Quantity	Unit
Butyl acetate [ecoinvent long-term to air]	0,0097	kg
Carbon dioxide [Inorganic emissions to air]	0,00041	kg
Carbon monoxide [Inorganic emissions to air]	8,06E-06	kg
Ethanol [ecoinvent long-term to air]	0,00194	kg
Methane [Organic emissions to fresh water]	3,26E-08	kg
Nitrogen dioxide [Inorganic emissions to air]	4,10E-06	kg
Sulphur oxides [Inorganic emissions to air]	5,00E-07	kg
Toluene [ecoinvent long-term to air]	0,00399	kg

Table 6. Transportation distances considered in the case study and displayed in Figure 2 and Figure 3

Type of material	Transport distance [km]	Origins/Destinations
Bituminous mixtures with CR (Figure 2)		
Steel blade	286	Production of steel blade/Crumb rubber plant
Plastic big bag	286	Production of plastic big-bag/Crumb rubber plant
ELT	60	ELT stock/Crumb rubber plant production
Crumb rubber	532	Crumb rubber plant production/Asphalt plant
Bitumen	100	Refinery/Asphalt plant
Aggregates	75	Quarry/Asphalt plant
CR mixtures	80	Asphalt plant /Construction site
Bituminous mixtures with RAP (Figure 3)		
RAP	-	The RAP stock is present at the asphalt plant
Bitumen	100	Refinery /Asphalt plant
Aggregates	75	Quarry/Asphalt plant
RAP mixture	80	Asphalt plant/Construction site

Table 7. Equations that provide the potential relative environmental improvement in each category depending on the degree of blending between aged and virgin bitumen

Impact category and acronyms	Potential relative life cycle environmental impacts improvements (%)	Coefficient of determination (R ²)
Climate change (<i>CC</i>)	$\Delta CC = 0.063DoB + 6.569$	0.999
Fossil depletion (<i>FD</i>)	$\Delta FD = 0.250DoB + 2.283$	0.999
Freshwater ecotoxicity (<i>FEc</i>)	$\Delta FEc = 0.201DoB + 4.247$	0.999
Freshwater eutrophication (<i>FEu</i>)	$\Delta FEu = 0.017DoB + 6.591$	0.998
Human toxicity (<i>HT</i>)	$\Delta HT = 0.227DoB + 4.437$	0.999
Marine ecotoxicity (<i>MEc</i>)	$\Delta MEc = 0.317DoB + 2.741$	0.999
Marine eutrophication (<i>MEu</i>)	$\Delta MEu = 0.042DoB + 10.023$	0.998
Ozone depletion (<i>OD</i>)	$\Delta MO = 0.006DoB + 0.971$	0.998
Particulate matter formation (<i>PM</i>)	$\Delta PM = 0.125DoB + 6.697$	0.985
Terrestrial acidification (<i>TA</i>)	$\Delta TA = 0.135DoB + 5.197$	0.991
Terrestrial ecotoxicity (<i>TE</i>)	$\Delta TE = 0.025DoB + 6.724$	0.921
Water depletion (<i>WD</i>)	$\Delta WD = 0.003DoB + 2.211$	0.949

Table 8. Ranking of the impact categories resulting from the differences in the degree of blending between virgin and aged binder and the consequent reduction of virgin bitumen consumption

Ranking	Impact category	Range of improvement between black rock and full blending [%]
1	Marine ecotoxicity	31.70
2	Fossil depletion	25.03
3	Human toxicity	22.65
4	Freshwater ecotoxicity	20.05
5	Terrestrial acidification	13.48
6	Particulate matter formation	12.54
7	Climate change	6.33
8	Marine eutrophication	4.22
9	Terrestrial ecotoxicity	2.45
10	Freshwater eutrophication	1.72
11	Ozone depletion	0.59
12	Water depletion	0.31
